Pytheas is a Python package for creating, running and postprocessing electrodynamic simulations. It is based on open source software Gmsh for creating geometries and mesh generation, and GetDP for solving the underlying partial differential equations with the finite element method.

It features built in models of:

- periodic media in 2D and 3D with computation of diffraction efficiencies
- scattering analysis in 2D and 3D
- bloch mode analysis of metamaterials
- treatment of open geometries with perfectly matched layers
- tools to define arbitrary permittivity distributions
- quasi-normal mode analysis
- two scale convergence homogenization
- tools for topology optimization in 2D
- built-in refractive index database

The complete project is documented for every submodule.

CONTENTS 1

2 CONTENTS

#### PYTHEAS.PERIODIC2D: 2D METAMATERIALS

The pytheas.periodic2D module implements the resolution of the scalar wave equation for TE and TM polarization for mono-periodic stuctures in 2D:

- subject to an incident plane wave (diffraction problem) and calculation of the diffraction efficiencies, absorption and energy balance.
- eigenvalues and eigenmodes (modal analysis)

#### 1.1 Classes

periodic2D.FemModel([analysis, pola, A, ])

A class for a finite element model of a 2D monoperiodic medium.

### 1.1.1 pytheas.periodic2D.FemModel

```
 \textbf{class} \  \, \texttt{pytheas.periodic2D.FemModel} \, (analysis='diffraction', \quad pola='TE', \quad A=1, \quad lambda0=1, \\ lambda\_mesh=1, \, theta\_deg=0, \, d=0.8, \, h\_sup=1, \, h\_sub=1, \\ h\_layer1=0.1, \quad h\_layer2=0.1, \quad h\_des=1.0, \quad h\_pmltop=1.0, \\ h\_pmlbot=1.0, \quad a\_pml=1, \quad b\_pml=1, \quad eps\_sup=(1+0j), \\ eps\_sub=(1+0j), \quad eps\_layer1=(1+0j), \quad eps\_layer2=(1+0j), \\ eps\_des=(1+0j), \quad eps\_incl=(1+0j))
```

A class for a finite element model of a 2D mono-periodic medium.

The model consist of a single unit cell with quasi-periodic boundary conditions in the x direction enclosed with perfectly matched layers (PMLs) in the y direction to truncate the semi infinite media. From top to bottom:

- PML top
- superstrate (incident medium)
- layer 2
- design layer: this is the layer containing the periodic pattern, can be continuous or discrete
- layer 1
- substrate
- PML bottom

#### **Parameters**

• analysis (str, default "diffraction") - Analysis type: either diffraction (plane wave) or modal (spectral problem)

```
• pola (str, default "TE") - Polarization case: either TE (E along z) or TM (H along
            z)
          • A(float, default 1) - Incident plane wave amplitude
          • lambda0 (float, default 1) - Incident plane wave wavelength in free space
          • lambda mesh (float, default 1) - Wavelength to use for meshing
          • theta_deg (float, default 0) - Incident plane wave angle (in degrees). Light
            comes from the top (travels along -y if normal incidence, theta_deg=0 is set)
          • d(float, default 0.8) - Periodicity
          • h_sup(float, default 1) - Thickness superstrate
          • h_sub(float, default 1) - Thickness substrate
          • h_layer1 (float, default 0.1) - Thickness layer 1
          • h_layer2 (float, default 0.1) - Thickness layer 2
          • h_des (float, default 1) - Thickness layer design
          • h_pmltop (float, default 1) - Thickness pml top
          • h_pmlbot (float, default 1) - Thickness pml bot
          • a_pml (float, default 1) - PMLs complex y-stretching parameter, real part
          • b pml (float, default 1) - PMLs complex y-stretching parameter, imaginary part
          • eps sup(complex, default (1 - 0 * 1 i)) - Permittivity superstrate
          • eps_sub(complex, default (1 - 0 * 1j)) - Permittivity substrate
          • eps_layer1 (complex, default (1 - 0 * 1j)) - Permittivity layer 1
          • eps_layer2 (complex, default (1 - 0 * 1j)) - Permittivity layer 2
          • eps_des (complex, default (1 - 0 * 1j)) - Permittivity layer design
          • eps_incl (complex, default (1 - 0 * 1j)) - Permittivity inclusion
cleanup()
    Clean gmsh/getdp generated files
diffraction efficiencies()
    Postprocess diffraction efficiencies
get_field_map(name)
    Retrieve a field map.
        Parameters name (str {'u', 'u_tot'}) - u (scattered field), u_tot (total field)
        Returns field
        Return type array, shape (self.Nix, self.Niy)
postpro_absorption()
    Compute the absorption coefficient
        Returns Q – Absorption coefficient
        Return type float
postpro fields (filetype='txt')
    Compute the field maps and output to a file.
```

**Parameters filetype** (str, default "txt") - Type of output files. Either txt (to be read by the method get\_field\_map in python) or pos to be read by gmsh/getdp.

#### postpro\_fields\_cuts()

Compute the field cuts in substrate and superstarte

#### **Returns**

- **u\_diff\_t** (*array-like*) Transmitted field cuts
- u\_diff\_r (array-like) Reflected field cuts

#### Examples using pytheas.periodic2D.FemModel

• Simulating diffraction by a 2D metamaterial

1.1. Classes 5

### PYTHEAS . SCATT2D: 2D SCATTERING

The pytheas.scatt2D module implements the resolution of the scalar wave equation for TE and TM polarization in 2D:

- subject to an incident plane wave or line source (diffraction problem)
- eigenvalues and eigenmodes (modal analysis)

#### 2.1 Classes

scatt2D.FemModel()

A class for a finite element model of a 2D medium

### 2.1.1 pytheas.scatt2D.FemModel

```
class pytheas.scatt2D.FemModel
```

A class for a finite element model of a 2D medium

#### A = None

flt – incident plane wave amplitude

#### Ni\_theta = None

int – number of theta points for computing the angular dependance of the modal coupling coefficients

#### $Nibox_x = None$

int – number of x interpolation points on the design box

#### $Nibox_y = None$

int – number of y interpolation points on the design box

#### Nin2f x = None

int – number of x interpolation points for near to far field calculations

#### $Nin2f_y = None$

int – number of y interpolation points for near to far field calculations

#### Nix = None

int – number of x points for postprocessing field maps

#### a\_pml = None

flt – PMLs parameter, real part

#### analysis = None

str – analysys type (either diffraction or modal)

```
b_pml = None
    flt – PMLs parameter, imaginary part
beam_flag = None
    beam?
cleanup()
    Clean gmsh/getdp generated files
dom des = None
    design domain number (check .geo/.pro files)
eps_des = None
    flt – permittivity scattering box
eps_host = None
    flt – permittivity host
eps_incl = None
    flt – permittivity inclusion
eps sub = None
    flt – permittivity substrate
h_pml = None
    flt – thickness pml
hx des = None
    flt - x - thickness scattering box (design)
hy_des = None
    flt - y - thickness scattering box
lambda0 = None
    flt – incident plane wave wavelength in free space
lambda0search = None
    flt – wavelength around which to search eigenvalues
lambda_mesh = None
    flt – wavelength to use for meshing
ls_flag = None
    line source position
nb_slice = None
    int – number of y slices points for postprocessing diffraction efficiencies
neig = None
    int – number of eigenvalues searched for in modal analysis
pola = None
    str – polarisation of the incident plane wave (either TE or TM)
scan_dist_ratio = None
    flt – such that scan\_dist = min(h\_sup, hsub)/scan\_dist\_ratio
theta deg = None
    flt – incident plane wave angle (in degrees). Light comes from the top (travels along -y if normal incidence,
    theta\_deg=0 is set)
xpp = None
     coords of point for PostProcessing
```

ypp = None
 coords of point for PostProcessing

2.1. Classes 9

## **CHAPTER**

# **THREE**

# **INDICES AND SEARCH**

- genindex
- modindex
- search

**CHAPTER** 

**FOUR** 

#### **EXAMPLES**

# 4.1 Material examples

Examples to show how to retrieve complex refractive index from a database, generating material patterns.

Note: Click here to download the full example code

### 4.1.1 Importing refractive index from a database

Retrieve and plot the refractive index of a material in the refractive index.info data.

```
# Code source: Benjamin Vial
# License: MIT

from pytheas.material.refractiveindex import *
from pytheas.tools.plottools import *
```

We can get the refractive index from tabulated data or a formula using the database in the pytheas.material module. We will import the measured data from the reference Johnson and Christy [JC1972]. We first specify the file yamlFile we want to import:

```
yamlFile = "main/Au/Johnson.yml"
```

We then get the wavelength bounds from the data (in microns) and create a wavelength range to interpolate:

```
bounds = getRange(yamlFile)
lambdas = np.linspace(bounds[0], bounds[1], 300)
```

Then get the refractive index data:

```
ncomplex = get_complex_index(lambdas, yamlFile)
epsilon = (ncomplex**2)
```

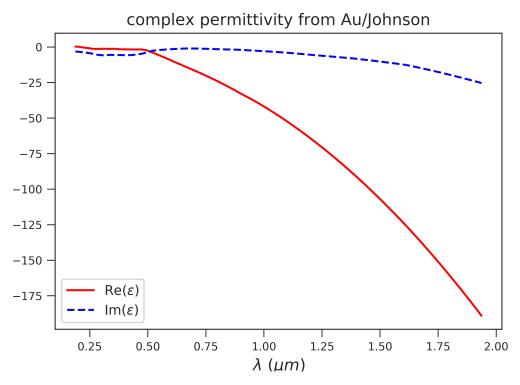

And finally plot it:

```
plt.close('all')
fig, ax = plt.subplots(1, figsize=(6, 4))
plt.plot(lambdas, epsilon.real, 'r-', label=r'Re($\varepsilon$)')
plt.plot(lambdas, epsilon.imag, 'b--', label=r'Im($\varepsilon$)')
plt.xlabel(r'$\lambda$ ($\mu m$)')
```

(continues on next page)

(continued from previous page)

```
plt.title("complex permittivity from " + yamlFile[5:][:-4])
plt.legend(loc=0)
plt.show()
```

Total running time of the script: (0 minutes 2.714 seconds)

# 4.2 Periodic 2D examples

Examples to show how to simulate a mono periodic medium (metamaterial) with the finite element method and post-processing the results (fields maps and diffraction efficiencies).

Note: Click here to download the full example code

### 4.2.1 Simulating diffraction by a 2D metamaterial

Finite element simulation of the diffraction of a plane wave a mono-periodic grating and calculation of diffraction efficiencies.

First we import the femmodel module and some utility functions:

```
# Code source: Benjamin Vial
# License: MIT

import numpy as np
```

(continues on next page)

(continued from previous page)

```
from pytheas.tools.plottools import *
from pytheas.material import genmat

from pytheas import periodic2D
from pytheas.periodic2D import FemModel, utils
```

Then we need to instanciate the class FemModel:

```
fem = FemModel()
```

The model consist of a single unit cell with quasi-periodic boundary conditions in the x direction enclosed with perfectly matched layers (PMLs) in the y direction to truncate the semi infinite media. From top to bottom:

- PML top
- superstrate (incident medium)
- layer 1
- design layer: this is the layer containing the periodic pattern, can be continuous or discrete
- layer 2
- · substrate
- · PML bottom

We define here the opto-geometric parameters:

```
# opto-geometric parameters
mum = 1e-6 #: flt: the scale of the problem (here micrometers)
fem.d = 0.4 * mum #: flt: period
fem.h_sup = 1. * mum #: flt: "thickness" superstrate
fem.h_sub = 1. * mum #: flt: "thickness" substrate
fem.h_layer1 = 0.1 * mum #: flt: thickness layer 1
fem.h_layer2 = 0.1 * mum #: flt: thickness layer 2
fem.h_des = 0.4 * mum #: flt: thickness layer design
fem.h_pmltop = 1. * mum #: flt: thickness pml top
fem.h_pmlbot = 1. * mum #: flt: thickness pml bot
fem.a_pml = 1 #: flt: PMLs parameter, real part
fem.b_pml = 1
              #: flt: PMLs parameter, imaginary part
fem.eps_sup = 1 #: flt: permittivity superstrate
fem.eps_sub = 11 #: flt: permittivity substrate
fem.eps_layer1 = 1 #: flt: permittivity layer 1
fem.eps_layer2 = 1 #: flt: permittivity layer 2
fem.eps_des = 1 #: flt: permittivity layer design
fem.lambda0 = 0.6 * mum #: flt: incident wavelength
fem.theta_deg = 0. #: flt: incident angle
fem.pola = "TE" #: str: polarization (TE or TM)
fem.lambda_mesh = 0.6 * mum #: flt: incident wavelength
#: mesh parameters, correspond to a mesh size of lambda_mesh/(n*parmesh),
#: where n is the refractive index of the medium
fem.parmesh\_des = 15
fem.parmesh = 13
fem.parmesh\_pml = fem.parmesh * 2 / 3
fem.type_des = "elements"
```

We then initialize the model (copying files, etc) and mesh the unit cell using gmsh

```
fem.getdp_verbose = 0
fem.gmsh_verbose = 0

fem.initialize()
mesh = fem.make_mesh()
```

#### We use the genmat module to generate a material pattern

```
genmat.np.random.seed(100)
mat = genmat.MaterialDensity()  # instanciate
mat.n_x, mat.n_y, mat.n_z = 2**7, 2**7, 1  # sizes
mat.xsym = True  # symmetric with respect to x?
mat.p_seed = mat.mat_rand  # fix the pattern random seed
mat.nb_threshold = 3  # number of materials
matprop = [1.4, 4 - 0.02 * 1j, 2]  # refractive index values

mat._threshold_val = np.random.permutation(mat.threshold_val)
mat.pattern = mat.discrete_pattern
fig, ax = plt.subplots()
mat.plot_pattern(fig, ax, cmap=cmap)
```

#### We now assign the permittivity

```
fem.register_pattern(mat.pattern, mat._threshold_val)
fem.matprop_pattern = matprop
```

Now were ready to compute the solution!

```
fem.compute_solution()
```

Finally we compute the diffraction efficiencies, absorption and energy balance

```
effs_TE = fem.diffraction_efficiencies()
print("efficiencies TE", effs_TE)
```

Out:

```
efficiencies TE {'R': 0.6211041345785192, 'T': 0.22865897491724108, 'Q': 0.

→1635944609994113, 'B': 1.0133575704951716}
```

It is fairly easy to switch to TM polarization:

```
fem.pola = "TM"
fem.compute_solution()
effs_TM = fem.diffraction_efficiencies()
print("efficiencies TM", effs_TM)
```

Out:

**Total running time of the script:** ( 0 minutes 5.457 seconds)
